

Direction of light from the Pole star (Polaris) - overhead for an observer at the (geographical) North pole.

Horizon for an observer at a latitude of θ ($^\circ$) North

Horizon for an observer at the (geographical) North pole

ϕ is the angular displacement, above the horizon, for an observer at a latitude of θ ($^\circ$) North

Horizon for an equatorial observer. Polaris would be on this observer's horizon.

Zenith

Axis of the Earth, at an angle of 23.5° with the vertical

From the above diagram,

$\angle \theta + \angle \lambda = 90^\circ$ ————— ①

Also, $\angle \phi + \angle \lambda = 90^\circ$ ————— ②

Combining ① and ②,

$\Rightarrow \underline{\underline{\angle \phi = \angle \theta}}$

The angle between the observer's horizon and the direction of light from Polaris, is the observer's latitude.
